## Load packages

```
library(matrixStats)
library(knitr)
library(tidyverse)
library(reshape2)
```

## Population Mean Example

Suppose you are interested in comparing the properties of the following 3 estimators for the mean  $\mu$  for  $n$  iid draws  $X_1, \dots, X_n$  with  $X_i \sim f(x)$

- Sample mean,  $T^1$
- Sample 15% trimmed mean,  $T^2$
- Sample median,  $T^3$

How would you expect the estimators to compare if the distribution of  $X_i$  is  $N(1,16)$ ?

### Step 1: Conduct the simulation

```
#Set the seed
set.seed(123456)

#Set up simulation parameters and truth
B = 500 #number of replicates
true.mu = 1 #true population mean
samp.size = 100 #sample size

#Create a function to loop or apply over
simulate <- function(n,mu,b){
  #generate data
  samp <- rnorm(n, mean=true.mu, sd=4)

  #calculate relevant quantities
  mean <- mean(samp)
  mean_trim <- mean(samp,trim=0.15)
  med <- median(samp)

  #return results
  return(c(mean,mean_trim,med))
}

#Simulate 500 times
# Option 1: use sapply
```

```

out.sapply <- sapply(1:B,simulate,n=samp.size,mu=true.mu) #this returns a 3xB matrix

# Option 2: use a for loop
out.for <- matrix(NA,B,3) #this will store results in a Bx3 matrix
for (b in 1:B){
  out.for[b,] <- simulate(n=samp.size,mu=true.mu,b)
}

```

## Step 2: Calculate the simulation quantities for each estimator

```

#OPTION 1: BASE R
# Mean
sim.mean <- colMeans(out.for)

# Bias
sim.bias <- colMeans(out.for-true.mu)

# Relative bias
sim.rel.bias <- colMeans(out.for-true.mu)/true.mu

# Standard deviation
sim.sd <- colSds(out.for)

# Mean squared error
sim.mse <- sim.bias^2 + sim.sd^2 #bias^2 + variance

# Combine all together
df.results <- data.frame(rbind(sim.mean,sim.bias,sim.rel.bias,sim.sd,sim.mse))

#OPTION 2: TIDYVERSE
df.out <- data.frame(out.for)
df.out %>% rename(mean=X1, `trimmed mean`=X2,median=X3) %>%
  melt() %>% group_by(variable) %>%
  summarise(sim.mean=mean(value),sim.bias=mean(value)-true.mu,
            sim.rel.bias=(mean(value)-true.mu)/true.mu,
            sim.sd = sd(value),
            sim.mse = (mean(value)-true.mu)^2 + sd(value)^2) #one command!

## No id variables; using all as measure variables

```

## Step 3: Present your results

```

kable(df.results,digits=3,align=rep('c', 2),
      col.names=c("mean","trimmed mean","median"))

```

	mean	trimmed mean	median
sim.mean	1.016	1.022	1.034
sim.bias	0.016	0.022	0.034
sim.rel.bias	0.016	0.022	0.034
sim.sd	0.404	0.422	0.508

	mean	trimmed mean	median
sim.mse	0.164	0.178	0.260

## Simulation exercise

```
library(MASS)
```

What happens if I exclude a covariate from my model? This follows from the first question on slide 6,

$$E[Y|X_1, X_2] = \beta_0 + \beta_1 X_1 + \beta_2 X_2$$

$$E[Y|X_1] = \alpha_0 + \alpha_1 X_1$$

The goal of this exercise is to say when  $\hat{\alpha}_1$  is unbiased for  $\beta_1$ .

1. Write a function that takes in  $b$ ,  $n$ ,  $\Sigma$ ,  $\lambda$ ,  $\beta_0$ ,  $\beta_1$ , and  $\beta_2$  and performs the following analysis:
  - Generate an  $n \times 2$  matrix containing the predictors  $X_1$  and  $X_2$  from a  $MVN(0_{2 \times 1}, \Sigma_{2 \times 2})$  where  $\Sigma_{2 \times 2}$  is the covariance matrix (the MASS package has a function called mvrnorm)
  - Generate an outcome vector with  $n$  observations  $\mathbf{y} = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \epsilon$  where  $\epsilon_i \sim N(0, \lambda^2)$  and  $X_1$  and  $X_2$  come from above
  - Fit the unadjusted model  $E[Y | X_1] = \alpha_0 + \alpha_1 X_1$
  - Return the coefficient estimates from the unadjusted model, i.e.  $\hat{\alpha}_0$  and  $\hat{\alpha}_1$
2. Use your function to repeat the above analysis  $B = 1000$  times with  $n = 500$ ,  $\lambda = 1$ ,  $\beta_0 = 2$ ,  $\beta_1 = 4$ , for the four scenarios:
  - Scenario 1:  $\beta_2 = 2$  and
 
$$\Sigma = \begin{bmatrix} 2 & 0.3 \\ 0.3 & 2 \end{bmatrix}$$
  - Scenario 2:  $\beta_2 = 0$  and
 
$$\Sigma = \begin{bmatrix} 2 & 0.3 \\ 0.3 & 2 \end{bmatrix}$$
  - Scenario 3:  $\beta_2 = 2$  and
 
$$\Sigma = \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}$$
  - Scenario 4:  $\beta_2 = 0$  and
 
$$\Sigma = \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}$$
3. For all scenarios, compute the bias of the coefficient estimates of  $\alpha_0$  and  $\alpha_1$ . Create a table with these results (columns should be scenarios).
4. Using a boxplot, plot the coefficient estimates for  $\alpha_1$  for each scenario. Indicate the true value of  $\beta_2$  on the plot.
5. Under which scenarios is  $\hat{\alpha}_1$  unbiased for  $\beta_1$ ? Any other observations?
